

# JSF 2: Programming Basics

## A Fast and Simplified Overview of JSF 2 Development

Originals of Slides and Source Code for Examples:

<http://www.coreservlets.com/JSF-Tutorial/jsf2/>

**Customized Java EE Training:** <http://courses.coreservlets.com/>

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

**For live training on JSF 2 and/or PrimeFaces,  
see <http://courses.coreservlets.com/>  
or email [hall@coreservlets.com](mailto:hall@coreservlets.com).**

**Taught by the author of *Core Servlets and JSP*, *More Servlets and JSP*, and this tutorial. Available at public venues, or customized versions can be held on-site at your organization.**

- Courses developed and taught by Marty Hall
  - JSF 2, PrimeFaces, servlets/JSP, Ajax, jQuery, Android development, Java 6 or 7 programming, custom mix of topics
  - Courses available in any state or country. Maryland/DC area companies can also choose afternoon/evening courses.
- Courses developed and taught by coreservlets.com experts (edited by Marty)
  - Spring, Hibernate/JPA, GWT, Hadoop, SOAP-based and RESTful Web Services

Contact [hall@coreservlets.com](mailto:hall@coreservlets.com) for details

# Topics in This Section

- **Simplified flow of control**
- **@ManagedBean and default bean names**
- **Default mappings for action controller return values**
- **Using bean properties to handle request parameters**

4

© 2013 Marty Hall

## Setup (Review from Previous Section)

**Customized Java EE Training: <http://courses.coreservlets.com/>**

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

# Setup Summary

- **JAR files**
  - JSF 2 JAR files required; JSTL 1.2 JARs recommended
    - Omit them in Glassfish 3, JBoss 6, and other Java EE 6 servers
- **faces-config.xml**
  - For this entire section: empty body (start/end tags only)
    - This tutorial section uses Java-based annotations and default mappings of action controller values to results pages. Later tutorial sections will look at explicit values in faces-config.xml.
- **web.xml**
  - Must have a url-pattern for \*.jsf (or other pattern you choose)
  - Usually sets PROJECT\_STAGE to Development
- **Accessing some-page.xhtml**
  - Use URL some-page.jsf (matches url-pattern from web.xml)

6

## faces-config.xml

```
<?xml version="1.0"?>
<faces-config xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
    http://java.sun.com/xml/ns/javaee/web-facesconfig_2_0.xsd"
  version="2.0">

</faces-config>
```

File is mostly empty, but the file must exist (in WEB-INF), and you must have legal start and end tags that designate JSF 2.0.

There will be no content inside the tags for any of the examples in this section. All examples in this section use default bean names (derived from the bean's class name with the first letter changed to lower case) and default results pages (derived from the action controller's return values).

7

# web.xml

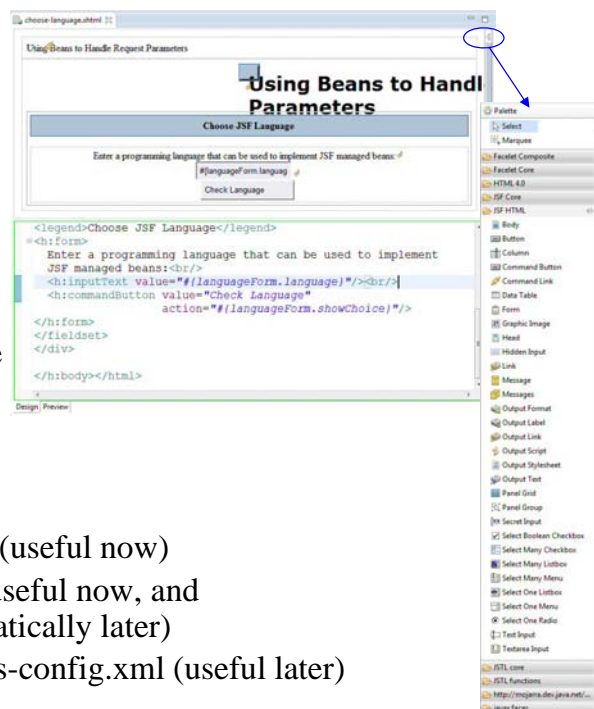

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app ... version="2.5">
  <servlet>
    <servlet-name>Faces Servlet</servlet-name>
    <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
  </servlet>
  <servlet-mapping>
    <servlet-name>Faces Servlet</servlet-name>
    <url-pattern>*.jsf</url-pattern>
  </servlet-mapping>
  <context-param>
    <param-name>javax.faces.PROJECT_STAGE</param-name>
    <param-value>Development</param-value>
  </context-param>
  <welcome-file-list>
    <welcome-file>index.jsp</welcome-file>
    <welcome-file>index.html</welcome-file>
  </welcome-file-list>
</web-app>
```

You must have a url-pattern for the FacesServlet, just as in JSF 1.x. You can optionally set the PROJECT\_STAGE, which is recommended during development and testing.

8

## Eclipse Support for JSF 2

- **Add JSF 2 project facet**
  - R-click project, Properties, Project Facets, check “JavaServer Faces 2”
    - The downloadable Eclipse projects from JSF 2.0 tutorial at [coreservlets.com](http://coreservlets.com) *already* have this facet set.
  - The first time you do it, you will have to give location of the JSF 2.0 (and JSTL) JAR files
    - Coreservlets sample projects use C:\mojarra-jsf-2.0
- **Benefits**
  - Visual previews of .xhtml files (useful now)
  - Palette of drag-and-drop tags (useful now, and will pick up PrimeFaces automatically later)
  - Lots of support for editing faces-config.xml (useful later)

9

# Eclipse Support: Issues

- **Problems**

- Poor web.xml file created when facet added
  - Creates a web.xml file with spurious entries, and without the very valuable Development PROJECT\_STAGE entry
- Editing .xhtml files
  - By default, they open in normal HTML editor, not smart editor that understands and previews the h: tags.

- **Solutions**

- web.xml file
  - Copy the web.xml version from jsf-blank or the “basics” project at coreservlets.com. Copy it into your project after adding facet.
- Editing .xhtml files
  - R-click .xhtml files, choose Open With, Web Page Editor
  - Or (better), you can make it automatic by going to Window, Preferences, General, Editors, File Associations, \*.xhtml, make Web Page Editor the default

10

# Eclipse JSF Support: Strategies

- **Copy and rename jsf-blank (or other project)**

- Instead of making new Dynamic Web project, then adding facet by hand.
  - Pros: Gets facet, web.xml, faces-config.xml, other files
  - Cons: have to fix the .component file as described later

- **Use JBoss Eclipse tools**

- JBoss has free tools for Eclipse that have improved JSF support. See <https://www.jboss.org/tools>
  - Pros: better .xhtml previews, more and better options to create projects, RichFaces previews
  - Cons: no palette, no PrimeFaces support, includes other tools in addition to JSF ones

11

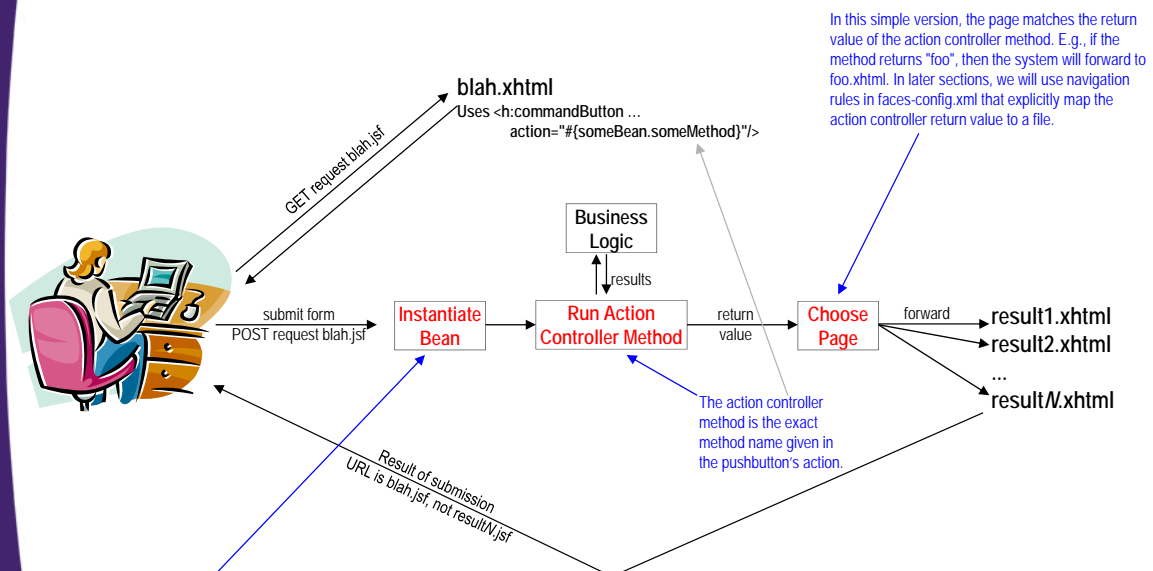

# Basic Structure of JSF 2 Apps

Customized Java EE Training: <http://courses.coreservlets.com/>

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

## JSF Flow of Control (Highly Simplified)

# Basic Structure of Facelets Pages

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://java.sun.com/jsf/html">
<h:head>
...
</h:head>
<h:body>
...
<h:form>
...
</h:form>
...
</h:body>
</html>
```

You use "facelets" – pages that use xhtml syntax – for all JSF 2.0 pages; you never use old-style JSP syntax. You always have `xmlns:h...`, `h:head`, `h:body`, and (for input forms) `h:form`. In later sections we will see that you sometimes also have `xmlns:f...` and/or `xmlns:ui...`. Results pages that do not also contain input elements can omit the `h:form` part.

No @taglib entries needed.

Remember that the URL does not match the real filename: you use `blah.xhtml` for the files, but `blah.jsf` for the URLs (or whatever ending matches the url-pattern in web.xml).

Finally, note that the "samples" folder of the jsf-blank project has a simple template file that contains the code shown here. Use that as a starting point for your own .xhtml files, rather than typing this all in by hand.

14

# Basic Structure of Managed Beans

```
@ManagedBean
public class SomeBean {
    private String someProperty;

    public String getSomeProperty() { ... }

    public void setSomeProperty() { ... }

    public String actionControllerMethod() {
        ...
    }

    // Other methods
}
```

Managed beans are Java classes that are declared with `@ManagedBean` or listed in `faces-config.xml`. More details will be given in the next tutorial sections, but for now the main points are:

- They are usually POJOs (they implement no special interfaces, and most methods have no JSF-specific argument or return types).
- They have pairs of getter and setter methods corresponding to each input element in the form.
- They have an action controller method that takes no arguments and returns a String. This is the method listed in the action of the `h:commandButton` in the input form.
- (They also typically have placeholders for derived properties – information that will be computed based on the input data. More on this in the next lecture on managed beans.)

15

# @ManagedBean Basics

Customized Java EE Training: <http://courses.coreservlets.com/>

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

## Main Points

- **@ManagedBean annotation**
  - `@ManagedBean`  
`public class SomeName { ... }`
  - You refer to bean with `#{someName.blah}`, where bean name is class name (minus packages) with first letter changed to lower case. Request scoped by default.
    - And “blah” is either an exact method name (as with action of `h:commandButton`), or a shortcut for a getter and setter method (as with value of `h:inputText`).
- **Return values of action controller method**
  - If action controller method returns “foo” and “bar” and there are no explicit mappings in `faces-config.xml`, then results pages are `foo.xhtml` and `bar.xhtml`
    - From same folder that contained the form

# Example

- **Idea**

- Click on button in initial page
- Get one of three results pages, chosen at random

- **What you need**

- A starting page
  - `<h:commandButton...action="#{navigator.choosePage}"/>`
- A bean
  - Class: Navigator (bean name above except for case)
  - `@ManagedBean` annotation
  - `choosePage` method returns 3 possible Strings
    - "page1", "page2", or "page3"
- Three results pages
  - Names match return values of `choosePage` method
    - `page1.xhtml`, `page2.xhtml`, and `page3.xhtml`

18

## start-page.xhtml

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://java.sun.com/jsf/html">
  <h:head>...</h:head>
  <h:body>
    ...
    <fieldset>
      <legend>Random Results Page</legend>
      <h:form>
        Press button to get one of three possible results pages.
        <br/>
        <h:commandButton value="Go to Random Page"
          action="#{navigator.choosePage}"/>
      </h:form>
    </fieldset>
    ...
  </h:body></html>
```

This means that when you press button, JSF instantiates bean whose name is navigator and then runs the `choosePage` method. This is same format as in JSF 1.x, but here name of bean is automatically derived from Java class name.

19

# Navigator.java

```
package coreservlets;
```

```
import javax.faces.bean.*;
```

```
@ManagedBean
```

```
public class Navigator {  
    private String[] resultPages =  
        { "page1", "page2", "page3" };
```

```
    public String choosePage() {  
        return(RandomUtils.randomElement(resultPages));  
    }  
}
```

Declares this as managed bean, without requiring entry in faces-config.xml as in JSF 1.x.

Since no name given, name is class name with first letter changed to lower case (i.e., navigator). You can also do @ManagedBean(name="someName"). See later section.

Since no scope given, it is request scoped. You can also use an annotation like @SessionScoped. See later section.

The randomElement method just uses Math.random to return an element from the array at random. Source code is in the downloadable Eclipse project.

Since there are no explicit navigation rules in faces-config.xml, these return values correspond to page1.xhtml, page2.xhtml, and page3.xhtml (in same folder as page that has the form).

20

# page1.xhtml

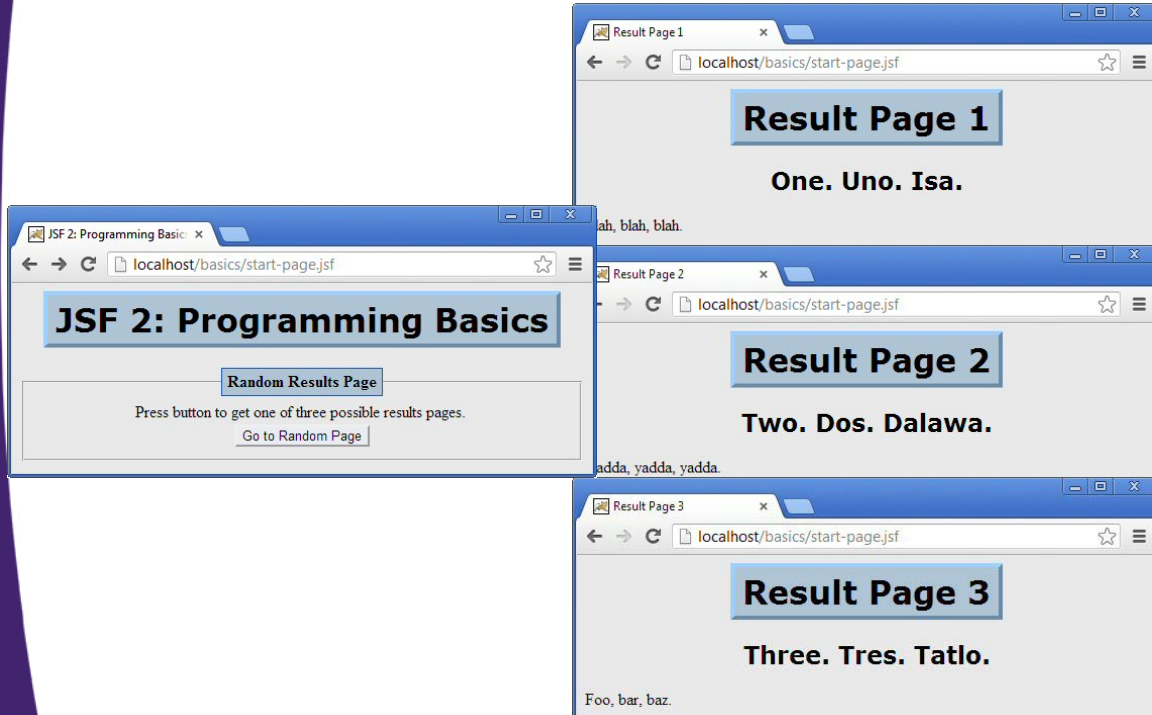

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"  
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">  
<html xmlns="http://www.w3.org/1999/xhtml"  
    xmlns:h="http://java.sun.com/jsf/html">  
    <h:head><title>Result Page 1</title>  
    <link href="./css/styles.css"  
        rel="stylesheet" type="text/css"/>  
    </h:head>  
    <h:body>  
  
        <table class="title">  
            <tr><th>Result Page 1</th></tr>  
        </table>  
        <p/>  
        <h2>One. Uno. Isa.</h2>  
        <p>Blah, blah, blah.</p>  
  
    </h:body></html>
```

I don't actually have any dynamic code in this simplistic example, but it is a good idea to plan ahead and always include h:head and h:body.

page2.xhtml and page3.xhtml are similar.

21

# Results

22

## Using Beans to Handle Request Parameters

Customized Java EE Training: <http://courses.coreservlets.com/>

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.

Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

# JSF Flow of Control (Updated but Still Simplified)

24

## Main Points

- **Input values correspond to bean properties**
  - `<h:inputText value=\"#{someBean.someProp}\"/>`
    - When form is submitted, takes value in textfield and passes it to `setSomeProp`.
      - Validation and type conversion (if any) is first. See later section.
    - When form is displayed, calls `getSomeProp()`. If value is other than null or empty String, puts value in field. See later section.
  - Same behavior as with bean properties in JSF 1.x
- **Beans are request scoped by default**
  - Bean is instantiated twice: once when form is initially displayed, then again when form is submitted.
  - Same behavior as with request-scoped beans in JSF 1.x.
- **Can use `#{bean.someProp}` directly in output**
  - Means to output result of `getSomeProp()`
    - Instead of `<h:outputText value=\"#{bean.someProp}\"/>` as in JSF 1

25

# Example

- **Idea**

- Enter name of a programming language
- Get one of
  - Error page: no language entered
  - Warning page: language cannot be used for JSF
    - Needs to output the language the user entered
  - Confirmation page: language is supported by JSF

- **New features you need**

- Bean
  - Properties corresponding to request parameters
- Input form
  - `<h:inputText value="#{languageForm.language}"/>`
- Results pages
  - `#{languageForm.language}` (for warning page)

26

# choose-language.xhtml

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://java.sun.com/jsf/html">
...
<h:body>
...
<fieldset>
<legend>Choose JSF Language</legend>
<h:form>
    Enter a programming language that can be used to implement
    JSF managed beans:<br/>
    <h:inputText value="#{languageForm.language}"/><br/>
    <h:commandButton value="Check Language"
        action="#{languageForm.showChoice}"/>
</h:form>
</fieldset>
...
</h:body></html>
```

When form is submitted, languageForm is instantiated and textfield value is passed to setLanguage.

Then, the showChoice method is called to determine the results page.

The value of h:inputText actually plays a dual role. When form is first displayed, languageForm is instantiated and getLanguage is called. If the value is non-empty, that result is the initial value of the textfield. Otherwise, the textfield is initially empty. When the form is submitted, languageForm is reinstantiated (assuming request scope) and the value in the textfield is passed to setLanguage. More on this dual behavior in the next tutorial section, but for now just be aware that your bean must have both getLanguage and setLanguage methods.

27

# LanguageForm.java (Top)

```
package coreservlets;
```

```
import javax.faces.bean.*;
```

```
@ManagedBean
```

```
public class LanguageForm {  
    private String language;
```

```
    public String getLanguage() {  
        return(language);  
    }
```

This will be automatically called by JSF when form is submitted.

```
    public void setLanguage(String language) {  
        this.language = language.trim();  
    }
```

Using #{languageForm.language} in the results page corresponds to the getLanguage method. Using <h:inputText value="#{languageForm.language}"/> in the input form means the textfield value will be passed to the setLanguage method. The names of instance variables (if any) is irrelevant. The next lecture will give the full rules for mapping the short form to the method names, but the simplest and most common rule is to drop "get" or "set" from the method name, then change the next letter to lower case.

28

# LanguageForm.java (Continued)

```
    public String showChoice() {  
        if (isMissing(language)) {  
            return("missing-language");  
        } else if (language.equalsIgnoreCase("Java") ||  
                   language.equalsIgnoreCase("Groovy")) {  
            return("good-language");  
        } else {  
            return("bad-language");  
        }  
    }
```

The action of h:commandButton is this exact method name, rather than a shortcut for a pair of getter and setter methods as with h:inputText.

```
    private boolean isMissing(String value) {  
        return((value == null) || (value.trim().isEmpty()));  
    }  
}
```

29

# missing-language.xhtml

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://java.sun.com/jsf/html">
<h:head>
...
</h:head>
<h:body>

<table class="title">
    <tr><th>Missing Language</th></tr>
</table>
<h2>Duh! You didn't enter a language!
(<a href="choose-language.jsf">Try again</a>)</h2>
<p>Note that using separate error pages for missing
input values does not scale well to real applications.
The later section on validation shows better approaches.</p>

</h:body></html>
```

30

# bad-language.xhtml

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://java.sun.com/jsf/html">
<h:head>
...
</h:head>
<h:body>

<table class="title">
    <tr><th>Bad Language</th></tr>
</table>
<h2>Use #{languageForm.language} in JSF?
Be serious!</h2>

</h:body></html>
```

Calls `getLanguage` and outputs the result.

In JSF 2.x you can use `#{result}` instead of `<h:outputText value="#{result}">` as was needed in JSF 1.x. Both approaches escape HTML characters, so you don't have to worry about the user entering HTML tags. Therefore, use the shorter approach shown here unless you need one of the options to `h:outputText` like `escape` (with a value of `false`), `rendered` (with a computed value), `id`, `converter`, etc. These are covered in later lectures.

31

# good-language.xhtml

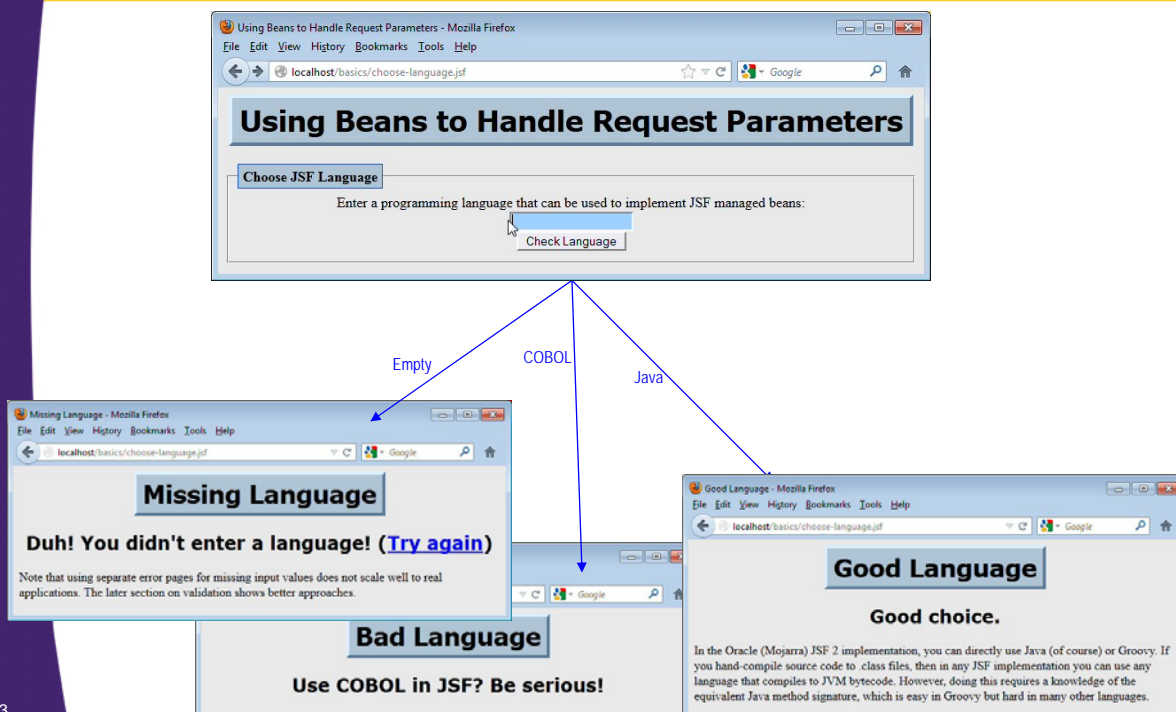

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
    "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:h="http://java.sun.com/jsf/html">
<h:head>
...
</h:head>
<h:body>

<table class="title">
  <tr><th>Good Language</th></tr>
</table>
<h2>Good choice.</h2>
<p>In the Oracle (Mojarra) JSF 2 implementation, ... </p>

</h:body></html>
```

32

## Results

33

## Interactive Example

**Customized Java EE Training:** <http://courses.coreservlets.com/>

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

## Simplified Banking App from Scratch (in 5 Minutes)

- **Make new project from jsf-blank**
- **Insert form that has button**
- **Make Java class with action controller to respond to button**
- **Make results pages**
- **Add textfield to form**
- **Extend Java class to have get/set methods**
- **Output the form values in results pages**
- **Extend action controller to calculate balance**
- **Output balance in results pages**

# Wrap-Up

**Customized Java EE Training:** <http://courses.coreservlets.com/>

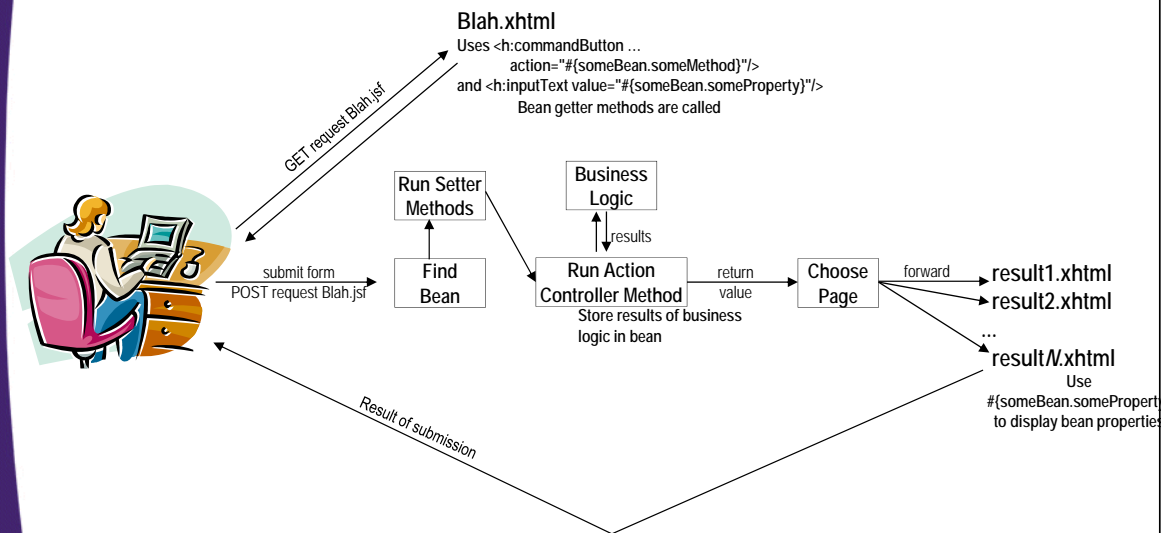

Java, JSF 2, PrimeFaces, Servlets, JSP, Ajax, jQuery, Spring, Hibernate, RESTful Web Services, Hadoop, Android.  
Developed and taught by well-known author and developer. At public venues or onsite at *your* location.

## Common Beginner Problems

- **JSF tags appear to be ignored**
  - You entered URL ending in *blah.xhtml* instead of *blah.jsf*
- **Error message about null source**
  - You have XML syntax error in main page. For example:
    - `<h:commandButton action="...">` (instead of `<h:commandButton action="..." />`)
    - Note that Eclipse is moderately helpful in finding XML syntax errors
- **Error message that view cannot be restored**
  - You went a very long time (e.g., during the lecture) without reloading the page or pressing a button.
  - Solution: copy the URL, restart browser, and paste in URL
- **New Java class not found by JSF**
  - If you add a *new* class that uses `@ManagedBean`, you must restart the server. (Also true if you edit `web.xml` or `faces-config.xml`, but we aren't doing either of those yet.)

# Highly Simplified JSF Flow of Control

38

## Summary

- **Forms (facelets pages)**
  - Declare h: namespace, use h:head, h:body, h:form
    - Use template from "samples" folder of jsf-blank
- **Managed beans**
  - Declare with @ManagedBean
    - Bean name is class name with first letter in lower case
  - Getter and setter for each input element
    - Form: `<h:inputText value="#{beanName.propertyName}"/>`
  - Action controller method
    - Form: `<h:commandButton action="#{beanName.methodName}"/>`
      - Return values become base names of results pages
- **Results pages**
  - Declare h: namespace, use h:head, h:body
  - Use `#{beanName.propertyName}` to output values

39

# Questions?

JSF 2, PrimeFaces, Java 7, Ajax, jQuery, Hadoop, RESTful Web Services, Android, Spring, Hibernate, Servlets, JSP, GWT, and other Java EE training.  
Also see JSF 2 tutorial and PrimeFaces tutorial.
